## Stoichiometry

## 1. What is stoichiometry?

This is when the BALANCED chemical reaction is used to determine proportions of chemicals involved in the reaction. The coefficients are viewed as mole counts.
2. What are the basic steps required for most stoichiometry calculations?

The basic steps that you will follow for most of the stoichiometric problems are.

1 - Make sure the reaction equation is balanced.
2 - The "backbone" calculation
You will be given information about substance $A$ and need to answer a question about substance $B$. The "backbone" is the general method for how you proceed with these calculations.

The conversion you use here depends on the starting units given in the equation For example x grams of $A$ is converted to moles of $A$ using the molar mass of $A$.

## 3. Consider:

$$
\mathrm{Al}_{(\mathrm{s})}+\mathrm{NH}_{4} \mathrm{ClO}_{4(\mathrm{~s})} \rightarrow \mathrm{Al}_{2} \mathrm{O}_{3(\mathrm{~s})}+\mathrm{AlCl}_{3(\mathrm{~s})}+\mathrm{NO}_{(\mathrm{g})}+\mathrm{H}_{2} \mathrm{O}_{(\mathrm{g})}
$$

What mass of ammonium perchlorate should be used for every kg of Al?

Step 1 - Balance the equation. Often times the equation will be given to you balanced, but always double check.

$$
3 \mathrm{Al}_{(\mathrm{s})}+3 \mathrm{NH}_{4} \mathrm{ClO}_{4(\mathrm{~s})} \rightarrow \mathrm{Al}_{2} \mathrm{O}_{3(\mathrm{~s})}+\mathrm{AlCl}_{3(\mathrm{~s})}+3 \mathrm{NO}_{(\mathrm{g})}+6 \mathrm{H}_{2} \mathrm{O}_{(\mathrm{g})}
$$

Step 2-Stoichiometry.

Perform the "backcbone" calculation....

$$
\begin{aligned}
& 1000 \mathrm{~g} \text { At } \frac{1 \mathrm{~mol} \mathrm{At}^{2}}{26.98 \mathrm{~g} A t} \frac{3 \mathrm{~mol}^{2} \mathrm{NH}_{4} \mathrm{ClO}_{4}}{3 \mathrm{~mol}-\mathrm{At}} \frac{117.50 \mathrm{~g} \mathrm{NH}_{4} \mathrm{ClO}_{4}}{1 \mathrm{~mol} \mathrm{NH}_{4} \mathrm{ClO}_{4}} \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}} \\
& =4.355 \mathrm{~kg} \mathrm{NH}_{4} \mathrm{ClO}_{4}
\end{aligned}
$$

As a matter of practice, you will report your answer in the same units you were given

## 4. Consider:

$$
5 \mathrm{CO}_{2(\mathrm{~g})}+55 \mathrm{NH}_{4}{ }_{(\mathrm{aq})}+76 \mathrm{O}_{2(\mathrm{~g})}^{\substack{\text { bacteria }}} \underset{\text { bacterial issue }}{\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}_{2}(\mathrm{~s})}+54 \mathrm{NO}_{2}{ }^{-}(\mathrm{aq})+52 \mathrm{H}_{2} \mathrm{O}_{(\mathrm{l})}+109 \mathrm{H}_{(\mathrm{aq})}^{+}
$$

How much bacterial tissue is produced in a treatment plant for every $1.0 \times 10^{4} \mathrm{~kg}$ of waste water containing $3.0 \% \mathrm{NH}_{4}{ }^{+}$by mass? Assume that $95 \%$ of the ammonium ions are consumed by bacteria.

The part of the waste water treated to produce bacterial tissue is $\mathrm{NH}_{4}{ }^{+}$. Thus only $3.0 \%$ of the mass of the water is involved in the reaction. So....
$\left(10,000,000\right.$ total grams of waste water) $(3.0 \%)=300,000 \mathrm{~g} \mathrm{NH}_{4}^{+}$
Additionally, the reaction is only $95 \%$ efficient. This means that only $95 \%$ of the $\mathrm{NH}_{4}{ }^{+}$will be consumed by the bacteria. Thus....
$\left(300,000 \mathrm{~g} \mathrm{NH}_{4}{ }^{+}\right)(95 \%)=285,000 \mathrm{~g} \mathrm{NH}_{4}{ }^{+}$treated.

$$
\begin{gathered}
285,000 \mathrm{~g}_{\mathrm{NH}}^{4}+\frac{1 \mathrm{~mol}^{+} \mathrm{NH}_{4}^{+}}{18.05 \mathrm{~g} \mathrm{NH}_{4}^{+}} \frac{1 \text { mol bacterial tissue }}{55 \mathrm{~mol}^{+\mathrm{NH}_{4}^{+-}}} \frac{113.13 \mathrm{~g} \text { bacterial tissue }}{1 \text { mol bacterial tissue }} \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}} \\
=32 \mathrm{~kg}
\end{gathered}
$$

5. What is a limiting reactant? How does it affect a reaction?

Reactant/reagent used up first in a reaction. The limiting reactant puts a cap on the amount of product that can be produced.
6. What clue indicates that you are dealing with a limiting reactant stoichiometry calculation?

If you are given information that would allow you to calculate for the moles of more than one reactant.
7. Consider:

$$
\underset{\text { chlorobenzene }}{2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}}+\underset{\text { chloral }}{\mathrm{C}_{2} \mathrm{HOCl}_{3}} \rightarrow \underset{\text { DDT }}{\mathrm{C}_{14} \mathrm{H}_{9} \mathrm{Cl}_{5}}+\mathrm{H}_{2} \mathrm{O}
$$

1142 g of chlorobenzene is reacted with 485 g of chloral.
a. What mass of DDT is formed?

You actually have to do part b before a. The first step is ALWAYS to figure out what the limiting reagent is. Never decide limiting reagent based on mass - many times it will work out but not always!

There are a few ways to go about determining the limiting reactant. One of the favored methods is to determine which reactant produces the least amount of product (it does not matter which product you choose, just as long as you pick the same product for both calculations).

For this problem, the calculations are as follows...

$$
\begin{aligned}
& 485 \mathrm{~g} \mathrm{C}_{2} \mathrm{HOCl}_{3} \frac{1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{HOCl}_{3}}{147.38 \mathrm{gCC}_{2} \mathrm{HOCl}_{3}^{-}} \cdot \frac{1 \mathrm{~mol} \mathrm{DDT}}{1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{HOCl}_{3}}=3.291 \mathrm{~mol} \mathrm{DDT}
\end{aligned}
$$

Based on the resulting information chloral is the limiting reagent as produces the least amount of product. Therefore the mass of DDT formed is...

$$
3.291 \text { mol-DDT } \frac{354.48}{1 \mathrm{~mol} D D \mathrm{~g}^{-}}=\begin{gathered}
1,167 \mathrm{~g} \mathrm{DDT} \\
\text { produced }
\end{gathered}
$$

## b. What is the limiting reactant?

As determined in part a chloral is the limiting reactant.
c. How much reactant is left?

No chloral remains as it limited the reaction.

There is, however, some chlorobenzene remaining. As previously stated there are multiple methods to solving. One of the commonly used techniques is demonstrated below.

$$
\begin{aligned}
& 3.291 \mathrm{~mol}-\mathrm{DDT} 2 \mathrm{~mol} \mathrm{C}_{6} \mathrm{HF}_{5} \mathrm{CT} 112.56 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}=740.9 \mathrm{~g} \text { of } \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl} \text { required } \\
& 1142 \mathrm{~g} \mathrm{C} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl} \text { present }-740.9 \mathrm{~g} \mathrm{C} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl} \text { used }=401 \mathrm{~g} \mathrm{C} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl} \text { remaining }
\end{aligned}
$$

## 8. What is the percent yield?

In a perfect world calculated would be the same as lab results. However, due to a variety of factors, we will never get $100 \%$ of our calculated value. The percent yield tells us what percentage of the expected value was actually obtained.
a. What is the $\mathrm{f} \frac{\text { actual yield }}{\text { theoretical yield }} \times 100=\%$ yield
9. Consider:

$$
\mathrm{P}_{4(\mathrm{~s})}+\mathrm{F}_{2(\mathrm{~g})} \rightarrow 4 \mathrm{PF}_{3(\mathrm{~g})}
$$

How many grams of $\mathrm{F}_{2}$ are needed to produce 120.0 g of $\mathrm{PF}_{3}$ if the reaction has a $78.1 \%$ yield?

This question is a bit tricky in that they gave you the desired actual yield but when you are using stoichiometry you deal with theoretical values.

$$
\begin{aligned}
& \frac{\text { Actual Yield }}{\% \text { yield }} \times 100=\text { Theoretical Yield } \\
& \frac{120.0 \mathrm{~g}}{78.1 \%} \times 100=154 \mathrm{~g} \mathrm{PF}_{3}
\end{aligned}
$$
